DATA QUALITY CHECK

PlaySafe

First Inspection

The initial inspection showed that the dataset contains several data quality issues that need to be addressed before modelling.

The main issues identified are:

- Data types: numerical and date variables are stored as strings.
- Missing data: several injury-related fields contain empty values.
- Inconsistent formats: values such as height, days out and dates are stored in different text formats.
- Inconsistent values: matches_missed contains both empty values and "-".
- Redundant information: current_age_x and current_age_y appear to represent similar information.
- Encoding issues: some player names contain incorrectly encoded characters.

One important quality concern is that missing injury information cannot automatically be interpreted as "no injury". This needs to be considered when defining the target variable.

These issues will be addressed during the data cleaning phase before EDA and modelling.
